

Attestcoin already proves the roots. This is where they live.

`hindsight.run` — the runtime · `mandate.hindsight.run` — the desk

Every Attestcoin query proves a run of Ethereum block roots — then lets them go.

A readability query carries a continuity proof: an array of transaction Merkle roots chained by digest up to a stored attestation. 0x0FD2 verifies the whole chain, so acceptance binds *every* root in it.

Then the call returns and the roots are dropped. The next question about the same block pays for the same proof again.

This is not a flaw. Verifying is not the same job as remembering. It is the only part worth changing.

MEASURED ON THE LIVE PROVER, CHAINKEY 3	
BLOCK AGE	ROOTS PER QUESTION
fresh	1
1 day – 90 days	41
180 days	841
Paid by every asker, every time. Kept by nobody.	

Three ownerless contracts. Each reads only the one below it.

LAYER	CONTRACT	DOES	OWNER
L0 • memory	EthereumMirror	Keeps every root the precompile verified. A <i>sealed span</i> proves a range is gap-free once and records it. Frozen IMirror: a second question in a held block is a view — no prover, no 0x0FD2, no wallet.	none
L1 • files	AbsenceRegistryV3	Bonded statements: “no such event about X in this range” and “these are all of them”. Anyone may refute with the transaction; half the bond to them, half burned. A standing claim is economic , and labelled so everywhere.	none
L2 • refusal	UnderwritingDesk	Reads the archive and the files, and pays or refuses — naming the fact. No score, nothing minted, nothing transferable, no number.	none

Above them: SubjectBinding (an Ethereum address signs for the Creditcoin key that speaks for it) and Cover (insurance on an open claim, settled by the hunt). No pause key anywhere. No upgrade path anywhere.

All three precompiles, used for what each one is for.

0X0FD2 · BLOCKPROVER

Write once. `verifyAndEmit` notarises a height and the archive retains the full continuity array it bound. Every later verify is a Merkle path against stored state.

0X0FD3 · CHAININFO

Self-repair. Checkpoints every 1,000 blocks at any depth. Roots computed from public receipts, the digest chain walked from a checkpoint, the precompile asked to reject it — it does not. **The archive extends with the hosted prover switched off.**

0X0FD4 · ATTESTORSTASH

The ceiling. The desk may not lend more than the attesor quorum behind the source chain has bonded, read live on every decision. 4 attestors × 100 CTC today.

Receipt status is checked before any log is trusted. No state proof is claimed. No absence is called a proof.

Independence: the home page verifies a second transaction with 0x0FD2 deleted for the call — and the control, with the mirror deleted, fails — on every load.

Nothing on this slide is a target.

2,684 / 0

differential checks against the live precompile, including forgeries / divergences

29 · 13 · 13.5

claims on the board · refuted by the hunt · tCTC burned

303,301

Sepolia heights, one unbroken run — a different chain is a different file

Every number above is written to `deployments.json` by `measure.ts` from chain state, graded in `CLAIMS.md`, and checked live at `hindsight.run/status`.

Paste an address. The desk pays, or refuses and names the transaction.

Four rows settle: **history on hand, what is on file, under challenge, verdict.** The verdict is last because it follows from the three above it.

Every answer is a live call to the contract that holds the money — the same assess that borrow gates on. A judge can run the refusal against a real liquidated mainnet borrower without anyone's key.

The word *precompile* does not appear on it.

THE REFUSALS, BY NAME

ArchiveTooShallow · ClaimUnderHunt · ProvenLiar ·
EventOnRecord · NoBondedCleanliness · NeedsBondedCover
· PoolCapReached · UnprovenSubject · AlreadyLent ·
DeskOutOfFunds

Each is an enum name beside a sentence. None is a number.

7,041,373 → 407,960. Same question, same block, both mined.

The first desk proved its ninety-day window by walking 648,000 held bits inside borrow: 2,532 cold reads. A lender that expensive is a screenshot of a view.

Now sealSpan does the walk once and records it; the caller hands the desk the spans it relies on; the desk re-checks adjacency, chain, length and freshness. A span cannot be sealed across a hole and a held bit is never unset — the same fact, for a handful of slots.

43,325 gas, cold, Foundry

The depth check.

test_gas_ninetyDayDepthCheckUnder80k fails the build above 80,000.

17.3× cheaper on Creditcoin

Two receipts, one block: the superseded desk and the live one, asked about the same address.

“Never liquidated” cannot be proven. It can be bonded, hunted, and burned.

/**hunt** lists every open bounty with what it pays, the measured gas to refute it (448k–4.0M) and the expected value. The board promises at least four documented lies open at all times; a replenisher keeps it so; a gate goes red if it slips.

The leaderboard is scored by tCTC **burned** — the only number you cannot farm by refuting yourself. Every name on it today is the house, and it says so.

Cover: an underwriter locks a payout on an open claim, a buyer pays a premium, and the claim’s own outcome decides who collects. No oracle — the hunt is the oracle. Run once with real money: bought for 0.05, the hunt refuted the claim, 1.0 tCTC collected. Four receipts.

Loans are sized to what a liar could not recover: ten times `enforceableLoss`, binding to the wei on a real Aave borrower.

The desk pays a Creditcoin key that has signed for its Ethereum address.

borrow underwrites `msg.sender` and takes no subject — a refusal must not be one parameter away from being washed. **SubjectBinding** closes the cost of that rule: an Ethereum address signs a transaction naming a Creditcoin key, proven against a held root, and the desk underwrites what that key speaks for. Still not a parameter: a liar would need a stranger's Ethereum key.

Replay-safe by Ethereum height. One record gets one loan however many keys its owner rotates through.

REQUIRESBINDING

An instrument may refuse any subject nobody has proven control of — `UnprovenSubject`. A fresh wallet with a true-of-everyone claim about itself is exactly what this refusal exists for, and the public gate shows the desk's own demo wallet refused by it.

Nothing minted. Nothing transferable. No number.

The same view, from wherever people already are.

SURFACE	WHAT IT DOES	CAN IT SPEND?
Telegram @MandateDeskBot	/assess 0x... · /hunt · /bounty, plus the Mini App. Webhook secret-verified; live.	no
Agents hindsight-run-mcp	Seven MCP tools: assess, verify, the five checks, hunt, usable, coverage, binding. The one that signs is not registered without a key.	not without a key
SDK · CLI hindsight-mirror	assess · checks · usable · bind · refute · mirrorIfNeeded.npx hindsight-mirror mandate assess 0x...	only where it says so
Solidity	A Foundry template whose tests delete 0x0FD2 and keep working. Two remappings, two frozen imports.	—
HTTP	/api/assess JSON · /api/certificate one-page PDF with the exact call to re-run · /api/dump · OpenAPI	no

The honesty machine runs in public, and it says these out loud.

- **No vetted stranger.** Both consumer contracts are the same person; every name on the leaderboard is the house; the only borrower paid is a house wallet. The site says so wherever a stranger would matter.
- **~110 days, not 180.** The deepening runs with the prover off at a measured rate; the run-unbroken gate will say when it gets there.
- **Nobody has bound an Ethereum address** — it needs an Ethereum wallet with gas, and the binding contract has a proof pipeline tested to the last step.
- **Cover is on open claims**, because a standing claim cannot be refuted and the registry's rule won over the plan.
- **The Korean is machine-assisted and unreviewed.** The hire-purchase corridor is not built.

CLAIMS.md grades every statement by its evidence and is generated from chain. /api/gates answers 503 the moment a promise breaks.

The better home for this cache is the node.

RIP: BlockRootCache. `rootOf[chainKey][height]` and a held bit, written as a side effect of every successful `verifyAndEmit;mirrorVerify` with no continuity argument; one new event. Every figure in the cost table is measured. It is in `docs/ENSHRINE.md`.

CEIP ask: archive capital from 180 days to a year · a CertiK review of L0 and L1 · Telegram distribution · one hire-purchase corridor with a real counterparty · a bounty for the first integrator we do not operate. Milestoned; every milestone a gate on `/status`.

“We would rather help you build B than be the reason it is not needed.”

— the last line of ENSHRINE, which does not change.
